

THINGS YOU SHOULD KNOW ABOUT HEART FAILURE WITH PRESERVED EJECTION FRACTION (DIASTOLIC DYSFUNCTION)

What is diastolic dysfunction?

- Heart failure is when the heart is unable to pump blood effectively.
- In some patients, this results from processes that make it harder for the heart to relax or fill between beats (diastolic dysfunction).
- Unlike in other patients with heart failure, a measurement of how well the heart beats, the ejection fraction, is normal.

What are risk factors for diastolic dysfunction?

- Older than 45 years.
- High blood pressure.
- Aortic stenosis (narrowing of the aortic heart valve).
- Atherosclerosis (clogged arteries).
- Diabetes.
- More common in women.

What are the symptoms?

- Shortness of breath.
- Irregular or abnormal heart beat.
- Fatigue.
- Light-headedness or fainting.

How is it diagnosed?

- Your doctor will ask you questions about your health and conduct a careful physical examination.
- He or she may order an imaging test called an echocardiography (a sonogram of the heart); this is often combined with a stress test to show how blood is flowing in the heart during exercise.

- Cardiac catheterization, in which a thin tube is inserted into the heart, may be warranted to learn more about its functioning.
- Blood tests may be done.

How is it treated?

- Smoking cessation, physical activity, and dietary changes.
- Treatment for conditions that can stiffen the left ventricle (high blood pressure, high cholesterol, diabetes).
- Medications may include:
 - Beta-blockers to slow the heart rate.
 - Calcium-channel blockers to reduce ventricular stiffness.
 - Angiotensin-converting enzyme (ACE) inhibitors.
 - Diuretics to reduce fluid accumulation.
 - Cardiac catheterization or surgery to fix problems, such as narrowed or obstructed blood vessels.
